

AND A CATEGORIFICATION OF THE FREED-QUINN LINE BUNDLE

joint work with Dan Berwick-Evans

Laura Murray

Apurva Nakade

Emma Phillips

Thanks to the AMS MRC on geometric representation theory and equivariant elliptic cohomology.

Plan:

1) Context / Motivation

2) Principal 2-group bundles: definitions and key properties

3) Applications

§1. CONTEXT AND MOTIVATION

Let  $G$  be a compact Lie group and fix  $\alpha \in H^3(G, \mathbb{C}^\times)$

↳ there are lots of fun things we can do with this data.

→ • Chern-Simons theory

•  $G$ -equivariant elliptic cohomology

→ • String structures

• Equivariant gerbes

• Higher representation theory

⋮

✱ Smooth 2-group  $\mathfrak{g} = \mathfrak{g}(G, \mathbb{C}^\times, \alpha)$

and its moduli space of principal 2-group bundles

Expectation

All of the above topics are meaningfully related to the space  $\text{Bun}_{\mathfrak{g}}(X)$ .

- Today we focus on the case that  $G$  is finite.

Fix input data:  $G$  - finite group

$A$  - an abelian Lie group with trivial  $G$ -action  
(e.g.  $A = U(1)$ )

$\alpha: G^{\times 3} \rightarrow A$  a 3-cocycle.

Chern-Simons story: ( $A = U(1)$ )

↳ Dijkgraaf-Witten theory.

Freed-Quinn: construct a line bundle  $\mathcal{L}$  on the moduli space of principal  $G$ -bundles on Riemann surfaces.

- For  $X$  a Riemann surface, we get a line bundle  $\mathcal{L}_X$  on  $\text{Bun}_G(X)$ .
- $\Gamma(\text{Bun}_G(X), \mathcal{L}_X)$  is exactly the vector space that Chern-Simons assigns to  $X$ .

Elliptic aside Restricting  $\mathcal{L}$  to the moduli space of principal  $G$ -bundles over elliptic curves, we obtain  $\tilde{\mathcal{L}}$ .

Ganter:  $\tilde{\mathcal{L}}$  is the natural home of twisted  $G$ -equivariant elliptic cohomology.

2-groups story  $[\alpha] \in H^3(G; A)$  classifies finite 2-groups

that are central extensions of  $G$  by  $*//A$ .

- To the representative  $\alpha$ , we associate  $\mathcal{G}$  with

• objects  $g \in G$       • morphisms  $\text{Hom}_{\mathcal{G}}(g, h) = \begin{cases} \emptyset & g \neq h \\ A & g = h \end{cases}$

•  $\otimes$ -structure:  $g \otimes h = gh$ .

associativity:  $(g \otimes h) \otimes k \xrightarrow{\sim} g \otimes (h \otimes k)$   
 $\uparrow \alpha(g, h, k) \in A$

- $\mathcal{G}$  can be viewed as a smooth 2-group, depending on the smooth structure of  $A$ .

(i.e. a group object in  $\mathcal{Bibun}$ )

- Today
- we'll define a moduli space (bicategory)  $\mathcal{Bun}_{\mathcal{G}}(X)$
  - we'll see there is a nice map  $\mathcal{Bun}_{\mathcal{G}}(X) \rightarrow \mathcal{Bun}_G(X)$
  - when  $X$  is a Riemann surface, this categorifies  $\mathcal{L}_X$ .
    - Sections of  $\mathcal{L}_X$  are then isomorphism classes of lifts from  $\mathcal{Bun}_G(X)$  to  $\mathcal{Bun}_{\mathcal{G}}(X)$ .
  - also applications to string structures/string geometry.

## §2. Principal 2-group bundles

Fix a smooth (finite) 2-group  $\mathcal{G}$  and smooth manifold.

Goal Define a bicategory of smooth 2-group bundles over  $X$

Our favourite definition: A **principal  $\mathcal{G}$ -bundle** on  $X$  is a smooth stack  $\mathcal{P} \rightarrow X$  equipped with an **action** of  $\mathcal{G}$  which is locally trivial:

$\exists$  surjective submersion  $u: Y \rightarrow X$  and an isomorphism of  $\mathcal{G}$ -stacks over  $Y$ :

$$d: u^* \mathcal{P} \xrightarrow{\sim} Y \times \mathcal{G}.$$

Cech data for  $\mathcal{P}$  - tells us how to glue  $\mathcal{G}$ -bundles from the trivial bundle on an open cover  $Y$ .

Note: the first level of gluing data is a bicartesian  $\Phi$

$$Y \times_X Y \times \mathcal{G} \xrightarrow{\Phi} Y \times_X Y \times \mathcal{G}$$

which we can assume is trivial as an  $A$ -bundle)

- $u: Y \rightarrow X$
- $g: Y \times_X Y \rightarrow G$  satisfying "cocycle" conditions.
- $\gamma: Y \times_X Y \times_X Y \rightarrow A$

Example: An  $A$ -gerbe over  $X$  is a principal  $\ast//A$ -bundle over  $X$ .

Cech data:  $u: Y \rightarrow X$   
 $\gamma: Y \times_X Y \times_X Y \rightarrow A$  a 2-cocycle.

Definition An  $A$ -2-gerbe is determined by

$u: Y \rightarrow X$   
 $\lambda: Y \times_X Y \times_X Y \times_X Y \rightarrow A$  a 3-cocycle.

Observe We have a forgetful functor  $\pi: \text{Bun}_G(X) \rightarrow \text{Bun}_G(X)$   
in terms of Cech data:  $(u, g, \gamma) \mapsto (u, g)$

Theorem [Berwick-Evans, C, Murray, Nakade, Phillips]

$\pi: \text{Bun}_G(X) \rightarrow \text{Bun}_G(X)$  is a torsor over the symmetric monoidal bicategory  $\text{Gerbe}_A(X)$ .

Sketch of proof The fibre over  $\overset{P_{\alpha}}{(u, g)}$  is given by the  $\gamma$ 's that complete the triple  $(u, g, \gamma)$ .

- $P$  determines a 3-cocycle  $\lambda_{P, \alpha} = g^* \alpha: Y \times_X^4 \rightarrow A$ :

$$(y_1, y_2, y_3, y_4) \mapsto \alpha(g(y_1, y_2), g(y_2, y_3), g(y_3, y_4))$$

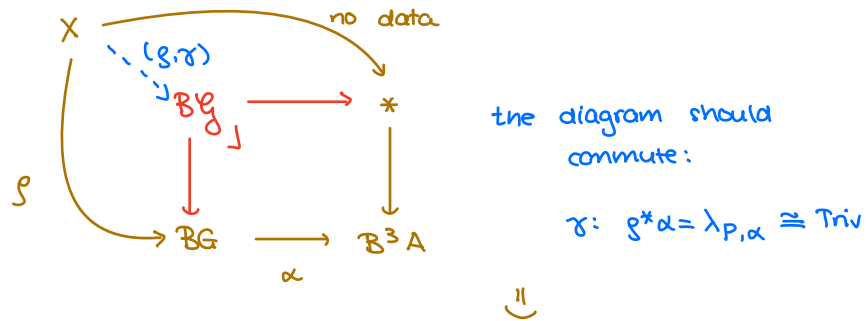

i.e. a 2-gerbe.

Claims 1) the data of  $\gamma$  is equivalent to a trivialisation of this 2-gerbe  $\lambda_{P, \alpha}$

2) the bicategory of trivialisations of a fixed 2-gerbe is a torsor over the symmetric monoidal bicategory of gerbes.  $\square$

Principal 2-group bundles in terms of classifying stacks:

Expectation  $\mathcal{G}$ -bundles are classified by maps  $X \rightarrow B\mathcal{G}$ .

Definition: A flat  $\mathcal{G}$ -bundle is a principal  $\mathcal{G}$ -bundle  $\leftarrow$  discrete topology.

Recall: Flat principal  $G$ -bundles are classified by homomorphisms

$$\pi_1(X) \rightarrow G$$

Theorem [BCMNP]

For  $X$  with contractible universal cover:

$$\begin{array}{ccc} \text{Bun}_{\mathcal{G}}^b(X) & \xrightarrow{\sim} & \text{Hom}_{\text{Bicat}}(*//\pi_1(X), *//\mathcal{G}) \\ \downarrow \pi & & \downarrow \pi \\ \text{Bun}_G^b(X) & \xrightarrow{\sim} & \text{Hom}_{\text{Cat}}(*//\pi_1(X), *//G) \cong \text{Hom}_{\text{Grp}}(\pi_1(X), G) // G \end{array}$$

A homomorphism  $\pi_1(X) \rightarrow \mathcal{G}$ :

- $g: \pi_1(X) \rightarrow G$  a homomorphism
- For all  $a, b \in \pi_1(X)$ .  $g(a)g(b) \xrightarrow{\sim} g(ab) \in \mathcal{G}$   
 $\uparrow$   
 $\gamma(a,b) \in A$  + cocycle condition

A natural transformation  $(g_1, \gamma_1) \Rightarrow (g_2, \gamma_2)$ :

- $t \in G$  s.t.  $\forall a \in G, t g_1(a) t^{-1} = g_2(a)$
- $\forall a \in G, t g_1(a) \xrightarrow{\sim} g_2(a) t \in \mathcal{G}$   
 $\uparrow$   
 $\psi(a) \in A$  + cocycle condition

• 2-morphisms are given by  $w \in A$ .

Theorem [BCMNP] The action of  $G$  on  $\text{Hom}_{\text{grp}}(\pi_1(X), G)$  lifts to an action of  $G$  on the bicategory  $\text{Hom}_{\text{bicat}}(*//\pi_1(X), *//\mathcal{G})$ . This gives  $\pi$  the structure of a cloven 2-fibration.

### §3. APPLICATIONS

3.A. Freed-Quinn line bundle ( $A = \text{U}(1)$ ,  $X$  a Riemann surface)

- We've seen that  $\pi: \text{Bun}_{\mathcal{G}}^b(X) \rightarrow \text{Bun}_G^b(X)$  is a cloven 2-fibration with fibres equivalent to  $\text{Gerbe}_{\text{U}(1)}^b(X)$
- We can now take isomorphism classes along fibres.
- Since isomorphism classes of gerbes are given by

$$H^2(X, \text{U}(1)) \cong \text{U}(1),$$

we obtain a principal  $\text{U}(1)$ -bundle on  $\text{Bun}_G^b(X)$ .

Theorem [BCMNP] The associated line bundle is the Freed-Quinn line bundle  $\mathcal{L}_X$ .

(cf. Willerton for  $X$  a torus)

### §4.B string structures

- We work with the string 2-group (not finite!)

$$1 \rightarrow *//\text{U}(1) \rightarrow \text{String}(n) \rightarrow \text{Spin}(n) \rightarrow 1.$$

- Starting from a finite group representation  $\rho_0: G_0 \rightarrow \text{SO}(n)$ , we produce a 2-group:

$$\begin{array}{ccccc}
 *//_{\text{U}(1)} & \longrightarrow & \mathcal{G} & \longrightarrow & \text{String}(n) \\
 & & \downarrow \lrcorner & & \downarrow \\
 \mathbb{Z}/2\mathbb{Z} & \longrightarrow & G & \xrightarrow{\mathcal{S}} & \text{Spin}(n) \\
 & & \downarrow \lrcorner & & \downarrow \\
 & & G_0 & \xrightarrow{\rho_0} & \text{SO}(n)
 \end{array}$$

Recall Let  $P_0 \rightarrow X$  be an oriented vector bundle with structure group  $G$ .

↳ a **spin structure** on  $P_0$  is a lift to a  $G$ -bundle  $P$ .

Definition [Schommer-Pries] a **string structure** on  $P$  is a lift to a  $\mathcal{G}$ -bundle  $\mathcal{P}$

Alternative definition [Waldorf] a **string structure** on  $P$  is a trivialization of the 2-gerbe  $\lambda_{P,\alpha}$

Theorem [BCMNP] The two definitions coincide.

- Let  $P \rightarrow X$  be a principal flat  $G$ -bundle and consider Chern-Simons theory for  $P$ ,  $\text{CS}_P$ .

Definition [Stolz-Teichner] a **geometric string structure** on  $P$  is a trivialization of  $\text{CS}_P$ .

- in particular, for suitable  $f: M^2 \rightarrow X$ ,  $\text{CS}_P(f)$  is a line, and we require a non-zero point in this line.

i.e. an isomorphism class of flat  $\mathcal{G}$ -bundle over  $f^*\mathcal{P}$

- this could be given by  $f^*\mathcal{P}$  for  $\mathcal{P}$  a flat lift of  $P$ .

So (part of the data of a trivialization of  $CS_p$ )

(part of the data of  $\mathcal{D} \in \pi^{-1}(p) \subset \text{Bun}_{\mathbb{C}/\mathbb{R}}^b(X)$ )

Work in progress: complete this story.

Thank you!
