

# Multiple zeta values in deformation quantization

Brent Pym

w/ Peter Banks and Erik Panzer

“Phase space” = manifold/variety  $X$  equipped with a **Poisson bracket**

$$\{-, -\} : \mathcal{O}_X \times \mathcal{O}_X \rightarrow \mathcal{O}_X$$

Axioms:

- 1  $\{f, g\} = -\{g, f\}$
- 2  $\{f, gh\} = \{f, g\}h + g\{f, h\}$
- 3  $\{f, \{g, h\}\} + \{g, \{h, f\}\} + \{h, \{f, g\}\} = 0$

Example (1d particle):  $X = \mathbb{R}_{(x,p)}^2 = T^*\mathbb{R}$ , functions  $\mathcal{O}_X = \mathbb{C}[x, p]$

$$\{f, g\} = \frac{\partial f}{\partial x} \frac{\partial g}{\partial p} - \frac{\partial f}{\partial p} \frac{\partial g}{\partial x} \qquad \{x, p\} = 1$$

Example (1d particle): replace  $x \rightsquigarrow \hat{x} = x \cdot$  and  $p \rightsquigarrow \hat{p} = -\hbar \partial_x$

$$A_{\hbar} = \frac{\mathbb{C} \langle \hat{x}, \hat{p} \rangle}{\hat{x}\hat{p} - \hat{p}\hat{x} = \hbar} \cong (\mathbb{C}[x, p], \star_{\hbar})$$

using Moyal–Groenewold star product:

$$f \star_{\hbar} g = \sum_{n=0}^{\infty} \frac{\hbar^n}{2^n n!} \sum_{i=0}^n (-1)^i \frac{\partial^n f}{\partial x^i \partial p^{n-i}} \frac{\partial^n g}{\partial x^{n-i} \partial p^i} = fg + \frac{1}{2} \hbar \{f, g\} + O(\hbar^2)$$

Definition (Bayen–Flato–Fronsdal–Lichnerowicz–Sternheimer 1978)

Let  $(X, \{-, -\})$  be a Poisson manifold. A **deformation quantization** of  $(X, \{-, -\})$  is a family of associative products  $\star_{\hbar}$  on  $\mathcal{O}_X$  such that

$$f \star_{\hbar} g = fg + \frac{1}{2} \hbar \{f, g\} + O(\hbar^2)$$

**Today:** only formal deformations

$$\begin{aligned} \star : \mathcal{O}_X \times \mathcal{O}_X &\rightarrow \mathcal{O}_X[[\hbar]] \\ f \star g &= fg + \underbrace{\hbar B_1(f, g)}_{=\frac{1}{2}\{f, g\}} + \hbar^2 B_2(f, g) + \dots \end{aligned}$$

**Basic question:** Does a quantization of  $(X, \{-, -\})$  always exist?

**Answer when  $(\{x_i, x_j\})_{i,j}$  nondegenerate (symplectic):** yes – Berezin, Deligne, Fedosov, Kirillov, Kostant, Schlichenmaier, Souriau, Toeplitz, ...

## Theorem (Kontsevich 1997)

Every smooth Poisson manifold  $X$  has a “canonical” quantization. In fact there is an equivalence

$$\underbrace{\{\text{Poisson brackets on } X\}}_{\sim} \cong \underbrace{\{\text{noncommutative deformations of } \mathcal{O}_X\}}_{\sim}$$

Precise statement is stronger:  $\wedge^\bullet T_X \cong CC^*(\mathcal{O}_X)$  as dg Lie algebras

Explicit formula when  $X = \mathbb{R}^n$ :

$$f \star g = fg + \hbar \left( \text{triangle diagram} \right) + \hbar^2 \left( \text{cross diagram} + \text{triangle with arrow} + \text{triangle with loop} \right) + \dots$$

$$\text{triangle with arrow diagram} = \left( \text{complicated integral} \right) \cdot \left( \text{derivatives of } f, g \text{ and } \{-, -\} \right)$$

Cattaneo–Felder: it’s the Feynman expansion for a disk correlator in a 2d TFT (Ikeda/Schaller–Strobl’s Poisson sigma model)

Given  $\{-, -\}$  in coordinates  $x_1, \dots, x_n$  on  $\mathbb{R}^n$ , want to compute  $f \star g$

$$\left( \begin{array}{c} \text{derivatives of} \\ f, g \text{ and } \{-, -\} \end{array} \right) := \sum_{i,j,k,l} (\partial_{x_i} f) \cdot (\partial_{x_j} \partial_{x_l} g) \cdot (\partial_{x_k} \{x_i, x_j\}) \cdot \{x_k, x_l\}$$

$$\rightsquigarrow \mathfrak{C}_{n,m} = \left\{ \begin{array}{c} \infty \\ \text{circle with } z_2, z_1 \text{ inside} \\ y_1, y_2 \text{ on the boundary} \end{array} \right\} / \text{holomorphic iso.}$$

$$\text{e.g. } \mathfrak{C}_{n,2} \cong \left\{ \begin{array}{c} \infty \\ \text{circle with } 0, 1 \text{ on the boundary} \end{array} \right\} \cong \mathbb{H}^n \setminus \{z_i = z_j\}_{i \neq j}$$

$$\rightsquigarrow 2\alpha_e := \frac{d \log(a, \bar{a}; b, \infty)}{2i\pi} + \frac{d \log(a, \bar{a}; \bar{b}, \infty)}{2i\pi}$$

$$\omega := \alpha_{e_1} \wedge \cdots \wedge \alpha_{e_N} \in 2^{-N} \mathbb{Z} \left\langle \frac{d \log f}{2i\pi} \mid f \text{ a cross ratio} \right\rangle \subset \Omega^\bullet(\mathfrak{C}_{n,m})$$

$$\left( \begin{array}{c} \text{complicated} \\ \text{integral} \end{array} \right) := \int_{\mathfrak{C}_{n,m}} \omega \in \mathbb{R}$$

$$\{f, g\} = \frac{\partial f}{\partial x} \frac{\partial g}{\partial p} - \frac{\partial g}{\partial x} \frac{\partial f}{\partial p} \quad \left( \begin{array}{cc} \{x, x\} & \{x, p\} \\ \{p, x\} & \{p, p\} \end{array} \right) = \left( \begin{array}{cc} 0 & 1 \\ -1 & 0 \end{array} \right)$$

$$\begin{aligned} f \star g &= fg + \hbar \left( \text{Diagram 1} \right) + \hbar^2 \left( \text{Diagram 2} + \text{Diagram 3} + \text{Diagram 4} \right) + \dots \\ &= fg + \hbar \left( \text{Diagram 1} \right) + \hbar^2 \left( \text{Diagram 2} \right) + \hbar^3 \left( \text{Diagram 3} \right) + \dots \\ &= \sum_{n=0}^{\infty} \frac{\hbar^n}{2^n n!} \sum_{i=0}^n (-1)^i \frac{\partial^n f}{\partial x^i \partial p^{n-i}} \frac{\partial^n g}{\partial x^{n-i} \partial p^i} \end{aligned}$$

The diagrams illustrate the expansion of the star product. Each diagram consists of two rows of nodes: two red nodes at the bottom and two blue nodes at the top. Arrows represent the terms in the expansion:

- Diagram 1:** A single blue node at the top with two arrows pointing down to the two red nodes.
- Diagram 2:** Two blue nodes at the top. The left blue node has two arrows pointing down to the two red nodes. The right blue node has two arrows pointing down to the two red nodes. There are also two arrows between the blue nodes: one from left to right and one from right to left.
- Diagram 3:** Two blue nodes at the top. The left blue node has two arrows pointing down to the two red nodes. The right blue node has two arrows pointing down to the two red nodes. There are also two arrows between the blue nodes: one from left to right and one from right to left. Additionally, there are dashed arrows forming a loop between the two blue nodes.
- Diagram 4:** Three blue nodes at the top. The left blue node has two arrows pointing down to the two red nodes. The middle and right blue nodes each have two arrows pointing down to the two red nodes. There are also arrows between the blue nodes: one from left to middle, one from middle to right, one from right to middle, and one from middle to left.

$X = \mathbb{R}^n$  with coordinates  $x_i$ , linear bracket

$$\{x_i, x_j\} = \sum c_{ij}^k x_k \quad \leftrightarrow \quad \text{Lie algebra } \mathfrak{g}$$

Similar analysis:

- Series truncates for  $f, g \in \mathbb{C}[x_i]$
- Can compute

$$x_i \star x_j - x_j \star x_i = \hbar \sum c_{ij}^k x_k$$

- Conclude

$$(\mathbb{C}[x_i], \star_{\hbar}) \cong \frac{\mathbb{C}\langle x_i \rangle}{x_i x_j - x_j x_i = \hbar \sum c_{ij}^k x_k} =: U(\mathfrak{g}, \hbar)$$

$$\{X, P\} = XP$$

$$X \star P = q(\hbar)XP \quad P \star X = q(-\hbar)XP$$

Our software:

$$q(\hbar) = 1 + \frac{\hbar}{2} + \frac{\hbar^2}{24} - \frac{\hbar^3}{48} - \frac{\hbar^4}{1440} + \frac{\hbar^5}{480} + \left( \frac{251\zeta(3)^2}{2048\pi^6} - \frac{17}{184320} \right) \hbar^6 + \dots$$

**Nevertheless:** algebra determined by

$$X \star P = \frac{q(\hbar)}{q(-\hbar)} P \star X = e^{\hbar} P \star X$$

Morally:  $X = e^x$  and  $P = e^p$  where  $\{x, p\} = 1$ .

$$\zeta(s) = \sum_{k \geq 1} \frac{1}{k^s}$$

**Theorem** (Euler 1735):  $\zeta(2m) = (-1)^{m+1} \frac{B_{2m}(2\pi)^{2m}}{2(2m)!} \in \mathbb{Q}\pi^{2m}$

**Open Question:** Is  $\zeta(2m+1) \in \mathbb{Q}(\pi)$ ?

**Conjecture:**  $\pi, \zeta(3), \zeta(5), \zeta(7), \dots$  are algebraically independent over  $\mathbb{Q}$ .

**Theorem** (Apéry 1978):  $\zeta(3) \notin \mathbb{Q}$

**Theorem** ((Ball-)Rivoal 2000): Infinitely many  $\zeta(3), \zeta(5), \zeta(7), \dots \notin \mathbb{Q}$

**Theorem** (Zudilin 2000): At least one of  $\zeta(5), \zeta(7), \zeta(9), \zeta(11) \notin \mathbb{Q}$

## Definition

A **normalized multiple zeta value (MZV)** of **weight  $n$**  is a number of the form

$$\tilde{\zeta}(n_1, \dots, n_d) = \frac{1}{(2i\pi)^n} \sum_{k_1 > k_2 > \dots > k_d \geq 1} \frac{1}{k_1^{n_1} k_2^{n_2} \dots k_d^{n_d}} \in \begin{cases} \mathbb{R} & n \text{ even} \\ i\mathbb{R} & n \text{ odd} \end{cases}$$

where  $n_1 \geq 2$  and  $n_1 + \dots + n_d = n$ .

Additional “honourary” normalized MZVs:

- $1 \in \mathbb{R}$  has weight 0
- $\frac{1}{2} = \frac{i\pi}{2i\pi} \in \mathbb{R}$  has weight 1

$$\tilde{\mathcal{Z}} := \mathbb{Z} \cdot \{\text{normalized MZVs}\} \subset \mathbb{C}$$

Weight filtration:

$$\begin{array}{ccccccc} \tilde{\mathcal{Z}}_0 & \subset & \tilde{\mathcal{Z}}_1 & \subset & \tilde{\mathcal{Z}}_2 & \subset & \dots \subset \tilde{\mathcal{Z}} \\ \parallel & & \parallel & & \parallel & & \\ \mathbb{Z} & \subset & \mathbb{Z} \cdot \frac{1}{2} & \subset & \mathbb{Z} \cdot \underbrace{\frac{\zeta(2)}{(2i\pi)^2}}_{=\frac{-1}{24}} & \subset & \dots \end{array}$$

Shuffle product:

$$\tilde{\mathcal{Z}}_m \tilde{\mathcal{Z}}_n \subset \tilde{\mathcal{Z}}_{m+n}$$

e.g.

$$\tilde{\zeta}(m)\tilde{\zeta}(n) = \tilde{\zeta}(m, n) + \tilde{\zeta}(n, m) + \tilde{\zeta}(n + m)$$

For unnormalized MZVs:

- $\mathbb{Q}$ -dimension of weight spaces conjectured by Zagier
  - ▶ Proven to be an upper bound (Terasoma, Deligne–Goncharov)
- $\mathbb{Q}$ -basis conjectured by Hoffman:  $\zeta(2s$  and  $3s)$ 
  - ▶ Proven to generate (Brown)

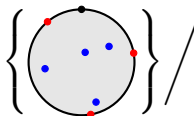

For normalized MZVs:

		<b><math>\mathbb{Z}</math>-module generators of <math>\tilde{\mathcal{Z}}_n</math></b>						
$n$	0	1	2	3	4	5	6	
real	1	$\frac{1}{2}$	$\frac{1}{24}$	$\frac{1}{48}$	$\frac{1}{5760}$	$\frac{1}{11520}$	$\frac{1}{2903040}$	
							$\frac{\zeta(3)^2}{128\pi^6}$	
imaginary				$\frac{i\zeta(3)}{8\pi^3}$	$\frac{i\zeta(3)}{16\pi^3}$	$\frac{i\zeta(3)}{192\pi^3}$	$\frac{i\zeta(3)}{384\pi^3}$	
						$\frac{i\zeta(5)}{64\pi^5}$	$\frac{i\zeta(5)}{128\pi^5}$	

- **Quantum groups:** coefficients of Drinfel'd associator
- **Knot theory:** coefficients of Kontsevich integral
- **Homotopical algebra:** formality of the operad  $E_2$
- **Algebraic geometry:** periods integrals on moduli space  $\mathcal{M}_{0,N}$   
(Brown 2006, conj. by Goncharov–Manin)
- **Physics:** values of certain Feynman integrals
- ...

Theorem (Brown 2011, building on Deligne–Goncharov, Levine, Voevodsky, Zagier, ...)

*All periods of unramified mixed Tate motives lie in  $\mathbb{Q}\tilde{\mathcal{Z}}[\frac{1}{2i\pi}]$ .*

$$\mathfrak{C}_{n,m} = \left\{ \text{circle with } n \text{ points} \right\} / \text{holomorphic iso.}$$

$$\mathcal{A}^\bullet(\mathfrak{C}_{n,m}) := \mathbb{Z} \left\langle \frac{d \log f}{2i\pi} \mid f \text{ a cross ratio} \right\rangle \subset \Omega^\bullet(\mathfrak{C}_{n,m})$$

### Theorem (Banks–Panzer–P.)

Suppose that  $\omega \in \mathcal{A}^{\dim}(\mathfrak{C}_{n,m})$  is absolutely integrable. Then

$$\int_{\mathfrak{C}_{n,m}} \omega \in \begin{cases} \tilde{\mathcal{Z}}_{n+m-2} & m > 0 \\ \tilde{\mathcal{Z}}_{n-1} & m = 0 \end{cases}$$

### Corollary (case $m = 2$ )

Coefficients at order  $\hbar^n$  in Kontsevich's star product lie in  $4^{-n} \tilde{\mathcal{Z}}_n \cap \mathbb{R}$

$$\tilde{\zeta}(n_1, \dots, n_d) = \frac{1}{(2i\pi)^n} \sum_{k_1 > k_2 > \dots > k_d \geq 1} \frac{1}{k_1^{n_1} k_2^{n_2} \dots k_d^{n_d}} = L_{n_1, \dots, n_d}(1)$$

in terms of **multiple polylogarithm**

$$L_{n_1, \dots, n_d}(z) := \frac{1}{(2i\pi)^n} \sum_{k_1 > k_2 > \dots > k_d \geq 1} \frac{z^{k_1}}{k_1^{n_1} k_2^{n_2} \dots k_d^{n_d}}$$

e.g.

$$L_1(z) = \sum_{k \geq 1} \frac{z^k}{k} = \frac{\log(1-z)}{2i\pi} \quad L_2(z) = \text{dilogarithm}$$

Alternate notation:

$$n_1, \dots, n_d \quad \leftrightarrow \quad s_1 \dots s_n = \underbrace{00 \dots 01}_{n_1} \underbrace{00 \dots 01}_{n_2} \dots \underbrace{00 \dots 01}_{n_d}$$

Check:

$$dL_{s_1 \dots s_n} = (-1)^{s_1} \frac{L_{s_2 \dots s_n} dz}{2i\pi(z - s_1)}$$

Rewrite

$$\tilde{\zeta}(n_1, \dots, n_d) = L_{s_1 \dots s_n}(1) \quad dL_{s_1 \dots s_n} = (-1)^{s_1} \frac{L_{s_2 \dots s_n} dz}{2i\pi(z - s_1)}$$

and therefore (Kontsevich, Le-Murakami)

$$\tilde{\zeta}(n_1, \dots, n_d) = (-1)^d \underbrace{\int_0^1 \frac{dt_1}{2i\pi(t_1 - s_1)} \int_0^{t_1} \frac{dt_2}{2i\pi(t_2 - s_2)} \cdots \int_0^{t_{n-1}} \frac{dt_n}{2i\pi(t_n - s_n)}}_{\int_0^1 s_1 \cdots s_n}$$

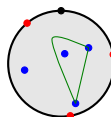

Then iterated integral

**NB:** diverges if  $s_1 = 1$  or  $s_n = 0$ , so “regularize”:  $\log(\epsilon) = 0$

$$\mathfrak{C}_{n,m} = \left\{ \text{disk with } m \text{ red and } n \text{ blue points} \right\} / \text{holomorphic iso.}$$

Choose  $s_0, s_1, \dots, s_{n+1} \in \{z_i, \bar{z}_i, y_i\}$ , define “disk polylog” (multivalued!)

$$L_{s_0; s_1 \cdots s_n; s_{n+1}} : \mathfrak{C}_{n,m} \rightarrow \mathbb{C}$$

The diagram shows a gray disk with a black boundary. There are  $m$  red points on the boundary and  $n$  blue points in the interior. A green path is drawn starting from a red point on the boundary, passing through the blue points, and ending at another red point on the boundary. An arrow points from this diagram to the integral expression.

$$\mapsto \int_{s_0}^{s_{n+1}} s_1 \cdots s_n$$

regularizing divergences via Deligne's tangential base points.

These functions and their differentials generate a locally constant subsheaf

$$\mathcal{A}^\bullet(\mathfrak{C}_{n,m}) \subset \mathcal{U}_{\mathfrak{C}_{n,m}}^\bullet \subset \Omega_{\mathfrak{C}_{n,m}}^\bullet$$

with monodromy unipotent for the weight filtration.

$$\text{Constants: } \tilde{\mathcal{Z}} \subset \mathcal{U}_{\mathfrak{C}_{n,m}}^0$$

## Theorem (BPP “de Rham theorem for disk polylogs”)

$\mathcal{U}^\bullet$  is a resolution of the constant sheaf  $\tilde{\mathcal{Z}}$  by acyclic local systems. Hence

$$H^\bullet(\mathcal{U}^\bullet(\mathfrak{C}_{n,m}), d) \cong H^\bullet(\mathfrak{C}_{n,m}; \tilde{\mathcal{Z}}).$$

## Sketch of proof.

Induction on  $n, m$  via  $f : \mathfrak{C}_{n,m} \rightarrow \mathfrak{C}_{n-k,m-j}$ .

Resolution:  $\mathbb{Z}$ -linear lift of Brown’s Poincaré lemma via fibrewise KZ equation  $dL = L' \cdot dz/(z - s)$ .

Acyclic: have  $\mathfrak{C}_{n,m} = K(\text{PureBraids}_n, 1)$ , show group cohomology of the monodromy representation vanishes (i.e.  $R^{>0} f_* \mathcal{U}_{\mathfrak{C}_{n,m}}^\bullet = 0$ ).  $\square$

## Corollary

Every volume form in  $\mathcal{U}^\bullet(\mathfrak{C}_{n,m})$  has a primitive in  $\mathcal{U}^\bullet(\mathfrak{C}_{n,m})$ .

## Theorem (BPP “Fubini theorem for disk polylogs”)

Given  $f : \mathfrak{C}_{n,m} \rightarrow \mathfrak{C}_{n-k,m-j}$  and integrable  $\omega \in \mathcal{U}^\bullet(\mathfrak{C}_{n,m})$ , have

$$\int_{\mathfrak{C}_{n,m}} \omega = \int_{\mathfrak{C}_{n-k,m-j}} \left( \int_{\text{fibres}} \omega \right) \quad \int_{\text{fibres}} \omega \in \mathcal{U}^\bullet(\mathfrak{C}_{n-k,m-j})$$

and weight drops by  $k$ . Main theorem:  $\omega \in \mathcal{A}^\bullet(\mathfrak{C}_{n,m})$  and  $f : \mathfrak{C}_{n,m} \rightarrow \text{pt.}$

$$\begin{aligned} & \int_{\text{disk}} \frac{Ldz \wedge d\bar{z}}{(z-s)(\bar{z}-z)} \\ &= \lim_{\epsilon \rightarrow 0} \int_{\partial_\epsilon \text{disk}} \tilde{L} \frac{dz}{z-s} \\ &= \sum \text{Res} + \int_{\text{outer cycle}} \end{aligned}$$

estimates + unipotent monodromy  
 $\rightsquigarrow$  weight drop

## Conjecture (BPP)

*Coefficients of the star product at  $\hbar^n$  generate  $\tilde{\mathcal{Z}}_n$ .*

Strategy: operadic motivic lift (in progress with Dupont and Panzer)

Convergence of power series? Motivic Galois action?

**Thank you!**
